

The Virginia Perennial Cool-Season Grass Forage Variety Report: A 3-Year Summary (2002-2004)

S.R. Smith, Forage Extension Specialist, Virginia Tech

C.D. Teutsch, Forage Research Agronomist, Southern Piedmont AREC

W.E. Thomason, Grains Extension Specialist, Virginia Tech

D.E. Starner, Superintendent, Northern Piedmont AREC

E.G. Rucker, Research Associate, Virginia Tech

G.B. Benson, Research Associate, Virginia Tech

D.R. Dixon, Senior Agriculture Manager, Northern Piedmont AREC

Perennial cool-season forage grasses are the foundation of ruminant livestock production systems in Virginia. Sound management of these grasses begins with proper species and variety selection. This report is a summary of forage variety trials performed with perennial cool-season grasses at Virginia Tech Agricultural Research and Extension Centers (ARECs) from 2002 through 2004. It includes trials seeded at the Southern Piedmont AREC (SPAREC) at Blackstone and at the Tidewater AREC, Suffolk, September 2001 and harvested for three years (2002 through 2004) (Tables 1 – 8 and 15 – 18). Data from two trials seeded at the Northern Piedmont AREC (NPAREC), Orange, in April 2002 and September 2002 and harvested for two years (2003 and 2004; Tables 9 – 14 and 19 – 24) also are included. The trials were conducted at multiple locations within the state in order to provide a range of environments.

The tables that follow include summary data of individual harvests within years (presented in pounds of dry matter per acre) and total season yields across years (presented in tons of dry matter per acre). The trials include tall fescue (*Festuca arundinacea* Schreb.) and orchardgrass (*Dactylis glomerata* L.). The varieties were submitted by or specifically requested of cooperating seed companies with appropriate standard varieties included as checks.

All entries in a trial at a location were harvested on the same dates, but harvest dates varied among locations and years. The goal was to harvest in May, June, August, and a final harvest between October and December for

a total of four harvests per year. Entries were planted in four replications of a randomized complete block design at each location. Individual plot size averaged 5 feet by 15 feet. All data were reported on a 100 percent dry matter basis; hay yields would be 10 percent to 15 percent higher. The variety trials were managed at high fertility levels. Phosphorus and potassium were maintained in the high range, and 225 to 300 pounds of nitrogen were applied per acre annually in split applications. At each harvest, plots were cut to a three-inch residual height with either a sickle or flail harvester.

Statistical analyses were performed for individual harvests within years and for total season yields across years. These analyses determine whether numerical differences are just random effects or indeed are "true" differences in performance among varieties. The term "LSD (0.05)" appears at the bottom of each table with an accompanying value under each column of data. An LSD (0.05) is the amount by which two varieties' yields in the same column must differ in order to be considered statistically, or meaningfully, different.

Precipitation has a profound effect on forage yield and persistence. Monthly average precipitation data are presented relative to long-term averages for each location at which the trials were conducted (Figs. 1, 2, and 3). At Orange and Blackstone, there was below average precipitation in 2002, above average precipitation in 2003, and near average precipitation in 2004 until fall when hurricane rains dramatically increased seasonal totals. Interestingly, 2002 was the driest year on record

VIRGINIA STATE UNIVERSITY

at Blackstone and 2003 was the wettest year on record. Tidewater irrigated its tall fescue plots in 2002, but not in 2003 and 2004.

When using this publication to select perennial grass forage varieties, it is important to 1) prioritize the relative importance of yield, persistence, and quality for the intended use of the forage and 2) understand the context within which these trials were conducted. These trials did not determine forage quality or palatability. These data reflect the yield and persistence of varieties under optimum management as monocultures. Neither variety compatibility with legumes nor soil adaptation were determined. Varieties that persisted well over several years in these trials may not necessarily persist well under grazing, poor fertility, or a broader range of soil types. Consult your local Extension agent for more information about forage varieties and management.

Acknowledgements

The researchers express their appreciation to the participating seed companies for their financial support of these trials. We are also indebted to Dean Sharron Quisenberry, Former Dean Andy Swiger, and Crop and Soil Environmental Sciences Department Head Steve Hodges for their support. Many thanks also to A. Ozzie Abaye and Glenn Johnson for their critical reviews of this publication. We want to thank Carol Wilkinson, SPAREC director, Jim Jones, former SPAREC director, and Fred Shokes, TAREC director, for their support of this research. Thanks, too, to the AREC employees, especially Steve Gulick and Alvin Hood at the NAREC and Ned Jones at the SPAREC, and the undergraduate student workers who provided valuable assistance in conducting the trials.
